## Abstract

In this paper, we derive linear complexity over  $F_p$  of the  $M$ -ary Sidel'nikov sequences using discrete Fourier transform. As an example, we represent the linear complexities of the ternary Sidel'nikov sequences. It turned out that the ternary Sidel'nikov sequences have the linear complexity nearly close to their periods.

## 1. Introduction

Linear complexity of sequences is one of the important properties of sequences in the secure communication and cryptography. A sequence having a large linear complexity implies the difficulty in the analysis of the sequence.

For a positive integer  $m$  such that  $M|p^m - 1$ , Sidel'nikov [8] constructed  $M$ -ary sequences (called *Sidel'nikov sequences*) of period  $p^m - 1$ , the out-of-phase autocorrelation magnitude of which is upper bounded by 4 [8]. Later, Lempel, Cohn, and Eastman [7] independently introduced the binary Sidel'nikov sequences of period  $p^m - 1$ . These binary sequences have near-ideal autocorrelation property which, under the condition of balancedness, is optimal.

Helleseeth and Yang [5] studied the linear complexity over  $F_2$  of the binary Sidel'nikov sequences. And Kyureghyan and Pott [6] extended their results using cyclotomic numbers. But these results are limited only to some special cases.

There is another approach to the study of the linear complexity of the binary Sidel'nikov sequences. Since Sidel'nikov sequences are constructed based on the finite field  $F_{p^m}$ , Helleseeth, Kim, and No [3] introduced the linear complexity over  $F_p$  of the binary Sidel'nikov sequences. But they showed only for small primes  $p$  such as  $p = 3, 5$ , and  $7$ . Recently, Helleseeth, Maas, Mathiassen, and Segers [4] derived the linear complexity over  $F_p$  of the binary Sidel'nikov sequences for a general prime  $p$ .

In this paper, we derive the linear complexity over  $F_p$  of the  $M$ -ary Sidel'nikov sequences using discrete Fourier transform. As an example, we represent the linear complexities of the ternary Sidel'nikov sequences. It turned out that the ternary Sidel'nikov sequences have the linear complexity nearly close to

their periods.

## 2. Preliminaries

For a sequence  $s(t)$  of period  $n = p^m - 1$ , the discrete Fourier transform is given by

$$A_i = \frac{1}{n} \sum_{t=0}^{n-1} s(t) \alpha^{-it}$$

and its inverse Fourier transform is given by

$$s(t) = \sum_{i=0}^{n-1} A_i \alpha^{it}$$

where  $\alpha$  is a primitive element of the finite field  $F_{p^m}$ .

The  $M$ -ary Sidel'nikov sequence is defined as follows:

**Definition 1** Let  $\alpha$  be a primitive element of  $F_{p^m}$ . For  $k = 0, 1, \dots, M - 1$ , define

$$S_k = \left\{ \alpha^{Ml+k} - 1 \mid 0 \leq l \leq \frac{p^m - 1}{M} - 1 \right\}.$$

Then  $M$ -ary Sidel'nikov sequence  $s(t)$  is defined as follows

$$s(t) = \begin{cases} k, & \alpha^t \in S_k, \\ k_0, & \alpha^t = -1. \end{cases}$$

□

When  $k_0 = 0$ , the Sidel'nikov sequence is balanced. In the following discussion, we will only consider the case of  $k_0 = 0$ .

The following theorem shows some combinatorial relation between a number and its  $p$ -ary expansion.

**Theorem 2** [Lucas' Theorem] [2] If  $p$  is a prime and  $N = \sum_{i=0}^I N_i p^i$ ,  $0 \leq N_i < p$ ,  $K = \sum_{i=0}^I K_i p^i$ ,  $0 \leq K_i < p$ , then

$$\binom{N}{K} \equiv \prod_{i=0}^I \binom{N_i}{K_i} \pmod{p}. \quad (1)$$

<sup>1</sup>This work was supported by University IT Research Center Project.

□

In this paper, we will call each  $\binom{N_i}{K_i}$  in (2) by a Lucas factor of  $\binom{N}{K}$ .

### 3. Linear Complexity of $M$ -ary Sidel'nikov Sequences

From the Blahut's theorem [1], the linear complexity of periodic sequences can be determined by computing the Hamming weight of their Fourier transform.

We will compute the Fourier transform of  $M$ -ary Sidel'nikov sequences for a general alphabet size  $M$ .

**Theorem 3** Let  $L = \frac{p^m-1}{M}$ ,  $n = p^m - 1$ , and  $p > M$ . For  $k_0 = 0$ , the Fourier transform of an  $M$ -ary Sidel'nikov sequence is derived as

$$nA_{-i} = \frac{n(M-1)}{2}(-1)^i - n(-1)^i \sum_{v=1}^{M-1} \frac{B_v(i)}{1 - \alpha^{vL}}$$

where  $B_v(i) = \binom{i}{vL}(-1)^{-vL}$ .

**Proof:** By Definition 1, Fourier transform of  $s(t)$  is written as

$$\begin{aligned} nA_{-i} &= \sum_{t=0}^{n-1} s(t)\alpha^{it} \\ &= k_0(-1)^i + \sum_{\alpha^t \in S_0 \setminus \{0\}} 0 \cdot \alpha^{it} + \sum_{\alpha^t \in S_1} \alpha^{it} \\ &\quad + \cdots + \sum_{\alpha^t \in S_{M-1}} (M-1)\alpha^{it}. \end{aligned}$$

Since  $k_0 = 0$ , we have

$$\begin{aligned} nA_{-i} &= \sum_{u=1}^{M-1} \sum_{l=0}^{L-1} u(\alpha^{Ml+u} - 1)^i \\ &= \sum_{u=1}^{M-1} u \sum_{l=0}^{L-1} \sum_{r=0}^i \binom{i}{r} (-1)^{i-r} \alpha^{(Ml+u)r} \\ &= \sum_{u=1}^{M-1} \sum_{r=0}^i u \binom{i}{r} (-1)^{i-r} \alpha^{ur} \sum_{l=0}^{L-1} \alpha^{Mlr}. \end{aligned}$$

The inner sum is equal to  $L$  for  $r = 0, L, \dots, (M-1)L$ , and it is equal to zero, otherwise. Therefore, we have

$$\begin{aligned} nA_{-i} &= \sum_{v=0}^{M-1} \sum_{u=1}^{M-1} Lu \binom{i}{vL} (-1)^{i-vL} \alpha^{uvL} \\ &= \sum_{v=0}^{M-1} L \binom{i}{vL} (-1)^{i-vL} \sum_{u=1}^{M-1} u \alpha^{uvL}. \end{aligned}$$

When  $v = 0$ , we have

$$\sum_{u=1}^{M-1} \frac{un}{M} \binom{i}{0} (-1)^i = \frac{n}{M} (-1)^i \sum_{u=1}^{M-1} u = \frac{n(M-1)}{2} (-1)^i.$$

Thus we have

$$\begin{aligned} nA_{-i} &= \frac{n(M-1)}{2} (-1)^i \\ &\quad + \sum_{v=1}^{M-1} L \binom{i}{vL} (-1)^{i-vL} \sum_{u=1}^{M-1} u \alpha^{uvL}. \end{aligned}$$

We can modify the inner sum in the second term as follows

$$\begin{aligned} \sum_{u=1}^{M-1} u \alpha^{uvL} &= \frac{1}{1 - \alpha^{vL}} \left( \sum_{u=1}^{M-1} \alpha^{uvL} - (M-1)\alpha^{vLM} \right) \\ &= \frac{-M}{1 - \alpha^{vL}}. \end{aligned}$$

Then we have

$$\begin{aligned} nA_{-i} &= \frac{n(M-1)}{2} (-1)^i - M \sum_{v=1}^{M-1} \frac{L \binom{i}{vL} (-1)^{i-vL}}{1 - \alpha^{vL}} \\ &= \frac{n(M-1)}{2} (-1)^i - n(-1)^i \sum_{v=1}^{M-1} \frac{\binom{i}{vL} (-1)^{-vL}}{1 - \alpha^{vL}}. \end{aligned}$$

From  $B_v(i) = \binom{i}{vL}(-1)^{-vL}$ , we have

$$nA_{-i} = \frac{n(M-1)}{2} (-1)^i - n(-1)^i \sum_{v=1}^{M-1} \frac{B_v(i)}{1 - \alpha^{vL}}.$$

□

**Theorem 4** Let  $D$  be the number of integer  $i$ ,  $0 \leq i \leq p^m - 2$  satisfying the relation

$$\frac{(M-1)}{2} = \sum_{v=1}^{M-1} \frac{B_v(i)}{1 - \alpha^{vL}}.$$

Then the linear complexity over  $F_p$  of the  $M$ -ary Sidel'nikov sequences of period  $n = p^m - 1$  equals

$$L_M = n - D.$$

□

And the following lemma can be used in the calculation of combinations which are included in  $B_v(i)$ .

**Lemma 5** For  $p = Md + 1$  and  $1 \leq j \leq d$ , we have

$$\binom{(M-1)d-j}{d-j} = \binom{(M-1)d+j}{d+j} \pmod{p}.$$

**Proof:** We will show that

$$\frac{d-i}{(M-1)d-i} = \frac{(M-1)d+i+1}{d+i+1} \pmod{p}. \quad (2)$$

From this equation, we have

$$(d-i)(d+i+1) = ((M-1)d+i+1)((M-1)d-i) \pmod{p}.$$

The left hand side(LHS) and the right hand side(RHS) are

$$LHS = d^2 + id + d - id - i^2 - i = d^2 + d - i^2 - i$$

$$\begin{aligned} RHS &= (M-1)^2 d^2 + (M-1)id + (M-1)d \\ &\quad - (M-1)id - i^2 - i \\ &= Md(Md+1) - 2d(Md+1) \\ &\quad + d^2 + d - i^2 - i \\ &= d^2 + d - i^2 - i \pmod{p}. \end{aligned}$$

Thus (2) is proved. Since  $\binom{(M-1)d-j}{d-j} \pmod{p}$  and  $\binom{(M-1)d+j}{d+j} \pmod{p}$  are obtained by multiplying  $\frac{d-i}{(M-1)d-i}$  and  $\frac{(M-1)d+i+1}{d+i+1}$ ,  $i = 0, 1, \dots, j-1$ , to  $\binom{(M-1)d}{d} \pmod{p}$ , respectively. Thus we have  $\binom{(M-1)d-j}{d-j} = \binom{(M-1)d+j}{d+j} \pmod{p}$ .  $\square$

#### 4. Linear Complexity of Ternary Sidel'nikov Sequences

Let  $\beta$  be a primitive element of  $F_p$ . From Theorem 4, we have to count the number of nonzero  $A_{-i}$ 's for  $M = 3$ .

**Corollary 6** For  $M = 3$ , we have

$$3 = \left( \binom{i}{L} - \binom{i}{2L} \right) \alpha^L + 2 \binom{i}{L} + \binom{i}{2L}. \quad (3)$$

**Proof:** For  $M = 3$ ,  $(-1)^L = 1$ . From Theorem 4, for  $M = 3$ , we have

$$\begin{aligned} 1 &= \sum_{v=1}^2 \frac{B_v(i)}{1 - \alpha^{vL}} = \frac{\binom{i}{L}}{1 - \alpha^L} + \frac{\binom{i}{2L}}{1 - \alpha^{2L}} \\ &= \frac{\binom{i}{L}(1 - \alpha^{2L}) + \binom{i}{2L}(1 - \alpha^L)}{1 - \alpha^L - \alpha^{2L} + \alpha^{3L}}. \end{aligned}$$

Since  $1 + \alpha^L + \alpha^{2L} = 0$ , we have

$$3 = \left( \binom{i}{L} - \binom{i}{2L} \right) \alpha^L + 2 \binom{i}{L} + \binom{i}{2L}. \quad \square$$

Then we can obtain the linear complexity of the ternary Sidel'nikov sequences as in the following theorem.

**Theorem 7** For  $p \equiv 2 \pmod{3}$ , the linear complexity of ternary Sidel'nikov sequences is given as

$$L_1 = p^m - C'_1$$

where

$$\begin{aligned} C'_1 &= \sum_{\substack{\sum_{i=2d+1}^{p-1} v_i = \frac{m}{2}, \sum_{i=2d+1}^{p-1} u_i = \frac{m}{2} \\ U=0 \pmod{p-1}, V=0 \pmod{p-1}}} \left[ (v_{2d+1}, \dots, v_{p-1})! \right. \\ &\quad \left. \times (u_{2d+1}, \dots, u_{p-1})! \right], \end{aligned}$$

$p = 3d+2$ ,  $\beta^{fk} = \binom{k}{d} \pmod{p}$ ,  $\beta^{gk} = \binom{k}{2d+1} \pmod{p}$ ,  $v_k$  is the number of  $\binom{k}{d}$  among the Lucas factors of  $\binom{i}{L}$ ,  $u_k$  is the number of  $\binom{k}{2d+1}$  among the Lucas factors of  $\binom{i}{L}$ ,  $U = \sum_{i=2d+1}^{p-1} (v_i f_i + u_i g_i)$ , and  $V = \sum_{i=2d+1}^{p-1} (v_i g_i + u_i f_i)$ .

**Proof:** There are three cases.

*Case 1.*  $0 \leq i < L$

In this case,  $\binom{i}{L} = 0$  and  $\binom{i}{2L} = 0$ . Then the equality (3) cannot be achieved. Therefore,  $A_{-i} \neq 0$  for all  $i$ ,  $0 \leq i < L$ .

*Case 2.*  $L \leq i < 2L$

In this case,  $\binom{i}{2L} = 0$ . Then we have

$$\binom{i}{L} \alpha^L = 3 - 2 \binom{i}{L}. \quad (4)$$

Since  $p \equiv 2 \pmod{3}$ , we have  $(\alpha^L)^{p-1} \neq 1$ . Therefore,  $\alpha^L \notin F_p$ . In (4), while left hand side is not an element of  $F_p$ , right hand side is an element of  $F_p$ . It is a contradiction. Therefore,  $A_{-i} \neq 0$ .

*Case 3.*  $2L \leq i < 3L$

In this case, from the equality (3), if  $\binom{i}{L} - \binom{i}{2L} \neq 0$ ,  $A_{-i} \neq 0$  since  $\alpha^L \notin F_p$  but  $\binom{i}{L}$  and  $\binom{i}{2L}$  are elements of  $F_p$ . If  $\binom{i}{L} - \binom{i}{2L} = 0$ , we have  $\binom{i}{L} = \binom{i}{2L} = 1 \pmod{p}$ .

In order to apply Lucas Theorem, we need to expand  $L$  as follows

$$L = \frac{p^m - 1}{3} = \frac{p^2 - 1}{3} (p^{m-2} + p^{m-4} + \dots + 1).$$

Since  $p = 3d + 2$ , we have

$$\frac{p^2 - 1}{3} = 3d^2 + 4d + 1 = d(3d+2) + 2d + 1 = dp + (2d+1).$$

Then we have

$$\begin{aligned} L &= dp^{m-1} + (2d+1)p^{m-2} + dp^{m-3} + (2d+1)p^{m-4} \\ &\quad + \dots + dp + (2d+1). \end{aligned}$$

Let  $i = \sum_{a=0}^{m-1} i_a p^a$ . By Lucas theorem, we have

$$\begin{aligned} \binom{i}{L} &= \binom{i_{m-1}}{d} \binom{i_{m-2}}{2d+1} \dots \binom{i_1}{d} \binom{i_0}{2d+1} \\ &= 1 \pmod{p}. \end{aligned} \quad (5)$$

Similarly,

$$\begin{aligned} 2L &= (2d+1)p^{m-1} + dp^{m-2} + (2d+1)p^{m-3} + dp^{m-4} \\ &\quad + \dots + (2d+1)p + d. \end{aligned}$$

Then we have

$$\begin{aligned} \binom{i}{2L} &= \binom{i_{m-1}}{2d+1} \binom{i_{m-2}}{d} \dots \binom{i_1}{2d+1} \binom{i_0}{d} \\ &= 1 \pmod{p}. \end{aligned} \quad (6)$$

Since  $\beta$  is a primitive element of  $F_p$ ,  $\beta^{fk} = \binom{k}{d} \bmod p$ , and  $\beta^{gk} = \binom{k}{2d+1} \bmod p$ , we can represent (5) and (6) as follows

$$\binom{i}{L} = \beta^{f^{i_{m-1}}} \beta^{g^{i_{m-2}}} \dots \beta^{f^{i_1}} \beta^{g^{i_0}} = \beta^0 \bmod p \quad (7)$$

$$\binom{i}{2L} = \beta^{g^{i_{m-1}}} \beta^{f^{i_{m-2}}} \dots \beta^{g^{i_1}} \beta^{f^{i_0}} = \beta^0 \bmod p. \quad (8)$$

Since  $v_k$  is the number of  $\binom{k}{d}$  among the factors of  $\binom{i}{L}$  in (5) and  $u_k$  is the number of  $\binom{k}{2d+1}$  among the factors of  $\binom{i}{L}$  in (6), we have  $\sum_{i=2d+1}^{p-1} v_i = \frac{m}{2}$  and  $\sum_{i=2d+1}^{p-1} u_i = \frac{m}{2}$ . Since all of the Lucas factors of  $\binom{i}{L}$  and  $\binom{i}{2L}$  are not equal to zero, from (7) and (8), we have  $U = \sum_{i=2d+1}^{p-1} (v_i f_i + u_i g_i) \equiv 0 \bmod p-1$  and  $V = \sum_{i=2d+1}^{p-1} (v_i g_i + u_i f_i) \equiv 0 \bmod p-1$ .

To count the number of  $i$  satisfying  $\binom{i}{L} = 1$  and  $\binom{i}{2L} = 1$ , we have to count the number of selection of  $v_j$  and  $u_j$ ,  $2d+1 \leq j \leq p-1$ , in (7) and (8). This can be done by the following multinomial

$$C'_1 = \sum_{\substack{\sum_{i=2d+1}^{p-1} v_i = \frac{m}{2}, \sum_{i=2d+1}^{p-1} u_i = \frac{m}{2} \\ U=0 \bmod p-1, V=0 \bmod p-1}} \left[ (v_{2d+1}, \dots, v_{p-1})! \right. \\ \left. \times (u_{2d+1}, \dots, u_{p-1})! \right]$$

where

$$(v_{2d+1}, \dots, v_{p-1})! = \frac{(v_{2d+1} + \dots + v_{p-1})!}{(v_{2d+1})! \dots (v_{p-1})!}.$$

We must rule out the case,  $i_m = \dots = i_0 = p-1$ . Then the linear complexity of ternary Sidel'nikov sequences is given as

$$L_1 = p^m - C'_1. \quad \square$$

**Example 8**  $m$  is even for  $p \equiv 2 \bmod 3$ . For  $p = 5$  and  $\beta = 3$ , we have

$$v_3 f_3 + v_4 f_4 + u_3 g_3 + u_4 g_4 = 0 \bmod 4$$

$$v_3 g_3 + v_4 g_4 + u_3 f_3 + u_4 f_4 = 0 \bmod 4.$$

Since  $f_3 = 1$ ,  $f_4 = 2$ ,  $g_3 = 0$ , and  $g_4 = 2$ ,

$$v_3 + 2v_4 + 2u_4 = 0 \bmod 4$$

$$2v_4 + u_3 + 2u_4 = 0 \bmod 4.$$

Therefore,  $v_3$  and  $u_3$  are multiples of 4 and  $v_4 + u_4$  is a multiple of 2. And  $v_3 + v_4 = \frac{m}{2}$  and  $u_3 + u_4 = \frac{m}{2}$ . Then the linear complexity of ternary Sidel'nikov sequences is written as

$$L_1 = p^m - \sum_{\substack{v_3 + v_4 = \frac{m}{2}, u_3 + u_4 = \frac{m}{2} \\ v_3 + 2v_4 + 2u_4 = 0 \bmod 4, \\ 2v_4 + u_3 + 2u_4 = 0 \bmod 4}} (v_3, v_4)! (u_3, u_4)! \\ = p^m - \left\{ \sum_{j=0}^{\lfloor \frac{m}{8} \rfloor} \binom{\frac{m}{2}}{4j} \right\}^2. \quad \square$$

From Lemma 5, we can easily obtain the following corollary.

**Corollary 9** For  $p = 3d + 1$  and  $1 \leq j \leq d$ , we have

$$\binom{2d-j}{d} = \binom{2d+j}{d} \bmod p. \quad \square$$

**Lemma 10** For  $p \equiv 1 \bmod 3$  and  $L \leq i < 3L$ , the number of  $i$  satisfying  $\binom{i}{2L} = 0$  and  $\binom{i}{L} = \frac{3}{\gamma+2} \bmod p$  is given as

$$E(d) - E(2d)$$

where

$$E(k) = \sum_{\substack{\sum_{j=k}^{p-1} v_j = m \\ \sum_{j=k}^{p-1} v_j f_j = f' \bmod p-1}} (v_k, \dots, v_{p-1})!$$

$\gamma = \alpha^L$ ,  $\beta^{f'} = \frac{3}{\gamma+2}$ ,  $\binom{k}{d} = \beta^{fk}$ , and  $v_k$  is the number of  $\binom{k}{d}$  among the Lucas factors of  $\binom{i}{L}$ .

**Proof:** By Lucas theorem, we have

$$\binom{i}{L} = \prod_{a=0}^{m-1} \binom{i_a}{d} = \beta^{f_{i_0}} \beta^{f_{i_1}} \dots \beta^{f_{i_{m-1}}} = \beta^{f'} \bmod p.$$

Since  $v_k$  is the number of  $\binom{k}{d}$  among the Lucas factors of  $\binom{i}{L}$ , we have

$$v_d + \dots + v_{p-1} = m.$$

Then we have

$$E(d) = \sum_{\substack{\sum_{j=d}^{p-1} v_j = m \\ \sum_{j=d}^{p-1} v_j f_j = f' \bmod p-1}} (v_d, \dots, v_{p-1})!.$$

If there exists the case that all  $i_a$ ,  $0 \leq a \leq m-1$ , are equal to  $p-1$ , then we have  $v_{p-1} = m$  and  $m f_{p-1} = f' \bmod p-1$ . From Corollary 9, we have  $\binom{3d}{d} = \binom{d}{d} = 1 \bmod p$ . Therefore,  $f_{p-1} = 0$ . But if  $f' = 0 \bmod p-1$ , then we have  $\frac{3}{\gamma+2} = 1$  and  $\gamma = 1$ , which is a contradiction since the order of  $\gamma$  is 3. Therefore, there is no case that all  $i_a$ ,  $0 \leq a \leq m-1$ , are equal to  $p-1$ .

Since  $\binom{i}{2L} = 0$ , we need to rule out the cases,  $\binom{i}{2L} \neq 0$  from  $E(d)$ .  $E(2d)$  is the number of  $i$  such that all the coefficients  $i_a$ ,  $0 \leq a \leq m-1$ , of its  $p$ -ary expansion are contained in the range  $2d \leq i_a < p-1$ , which corresponds to  $\binom{i}{2L} \neq 0$  and  $\binom{i}{L} = \frac{3}{\gamma+2} \bmod p$ . Thus, we must subtract  $E(2d)$  from  $E(d)$ . □

Similarly, we can obtain the following lemma.

**Lemma 11** For  $p \equiv 1 \bmod 3$  and  $2L \leq i < 3L$ , the number of  $i$  satisfying  $\binom{i}{L} = c_1 \neq 0$  and  $\binom{i}{2L} = c_2 \neq 0$  is given as

$$F_{c_1, c_2} = \sum_{\substack{\sum_{j=2d}^{p-1} v_j f_j = f' \bmod p-1 \\ \sum_{j=2d}^{p-1} v_j g_j = g' \bmod p-1 \\ v_{2d} + \dots + v_{p-1} = m}} (v_{2d}, \dots, v_{p-1})!$$

where  $c_1 = \beta^{f'}$ ,  $c_2 = \beta^{g'}$ ,  $\binom{k}{d} = \beta^{fk}$ , and  $\binom{k}{2d} = \beta^{gk}$ .  $\square$

**Theorem 12** For  $p \equiv 1 \pmod{3}$ , the linear complexity of ternary Sidel'nikov sequences is given as

$$L_2 = p^m - E(d) + E(2d) - \sum_{(\gamma+2)c_1 - (\gamma-1)c_2 = 3} F_{c_1, c_2}.$$

**Proof:** Since  $(\alpha^L)^{p-1} = (\alpha^d)^{p^m-1} = 1$ ,  $\alpha^L \in F_p$ . Let  $\alpha^L = \gamma$ . Then  $\gamma$  is an element of  $F_p$  with order 3. Equation (3) can be represented as

$$3 = (\gamma + 2) \binom{i}{L} - (\gamma - 1) \binom{i}{2L}. \quad (9)$$

There are two cases.

*Case 1)*  $0 \leq i < L$

Since  $\binom{i}{L} = 0$  and  $\binom{i}{2L} = 0$ , (9) cannot be achieved.

*Case 2)*  $L \leq i < 3L$

There are two cases satisfying (9):

(a)  $\binom{i}{2L} = 0$  and  $\binom{i}{L} = \frac{3}{\gamma+2} \pmod{p}$

(b)  $\binom{i}{L} = c_1$  and  $\binom{i}{2L} = c_2$ .

In this case,  $c_1$  and  $c_2$  have the same order. Then  $c_1 = 1$  and  $c_2 = 1$  are always valid. When  $i_a = p - 1$ ,  $0 \leq a \leq p - 1$ , from Corollary 9, we have  $f_{p-1} = 0$ ,  $g_{p-1} = 0$ , and  $v_{p-1} = m$ . Thus  $F_{1,1}$  contains the case for  $i_a = p - 1$ ,  $0 \leq a \leq p - 1$ .

From Lemma 10, we have the number of  $i$  satisfying (a). And from Lemma 11, we also have the number of  $i$  satisfying (b). And we must remove the case when all  $i_a$ 's are equal to  $p - 1$ .

Therefore, the linear complexity of ternary Sidel'nikov sequences for  $p \equiv 1 \pmod{3}$  is given as

$$L_2 = p^m - E(d) + E(2d) - \sum_{(\gamma+2)c_1 - (\gamma-1)c_2 = 3} F_{c_1, c_2}. \quad \square$$

**Example 13** For  $p = 7$ ,  $\beta = 3$ , and  $\gamma = 2$ , we have

$$f_2 = 0, f_3 = 1, f_4 = 3, f_5 = 1, f_6 = 0 \\ g_4 = 0, g_5 = 5, g_6 = 0.$$

Then we have

$$E(d) = \sum_{\substack{v_2 + \dots + v_6 = m \\ v_3 + 3v_4 + v_5 = 3 \pmod{6}}} (v_2, \dots, v_6)!$$

and

$$E(2d) = \sum_{\substack{v_4 + v_5 + v_6 = m \\ 3v_4 + v_5 = 3 \pmod{6}}} (v_4, v_5, v_6)!.$$

We can calculate the numbers  $c_1$  and  $c_2$  satisfying (9) and having the same order. As a result, we have  $(c_1, c_2) = (1, 1)$  and  $(5, 3)$ . Then we have

$$F_{1,1} = \sum_{\substack{v_4 + v_5 + v_6 = m \\ 3v_4 + v_5 = 0 \pmod{6}, 5v_5 = 0 \pmod{6}}} (v_4, v_5, v_6)!$$

and

$$F_{5,3} = \sum_{\substack{v_4 + v_5 + v_6 = m \\ 3v_4 + v_5 = 5 \pmod{6}, 5v_5 = 1 \pmod{6}}} (v_4, v_5, v_6)!.$$

Finally, we have

$$L_2 = p^m - E(d) + E(2d) - F_{1,1} - F_{5,3}. \quad \square$$
